Valuation of Load Flexibility Technologies

Sarah Smith, Berkeley Lab

The goal

is to assess the costs and benefits of load flexibility technologies to customers and the grid

The approach

is modeling widespread future adoption of technologies, present-day costs and performance, and hypothetical price signals

Initial results: effective DR from price response, and estimated grid benefits

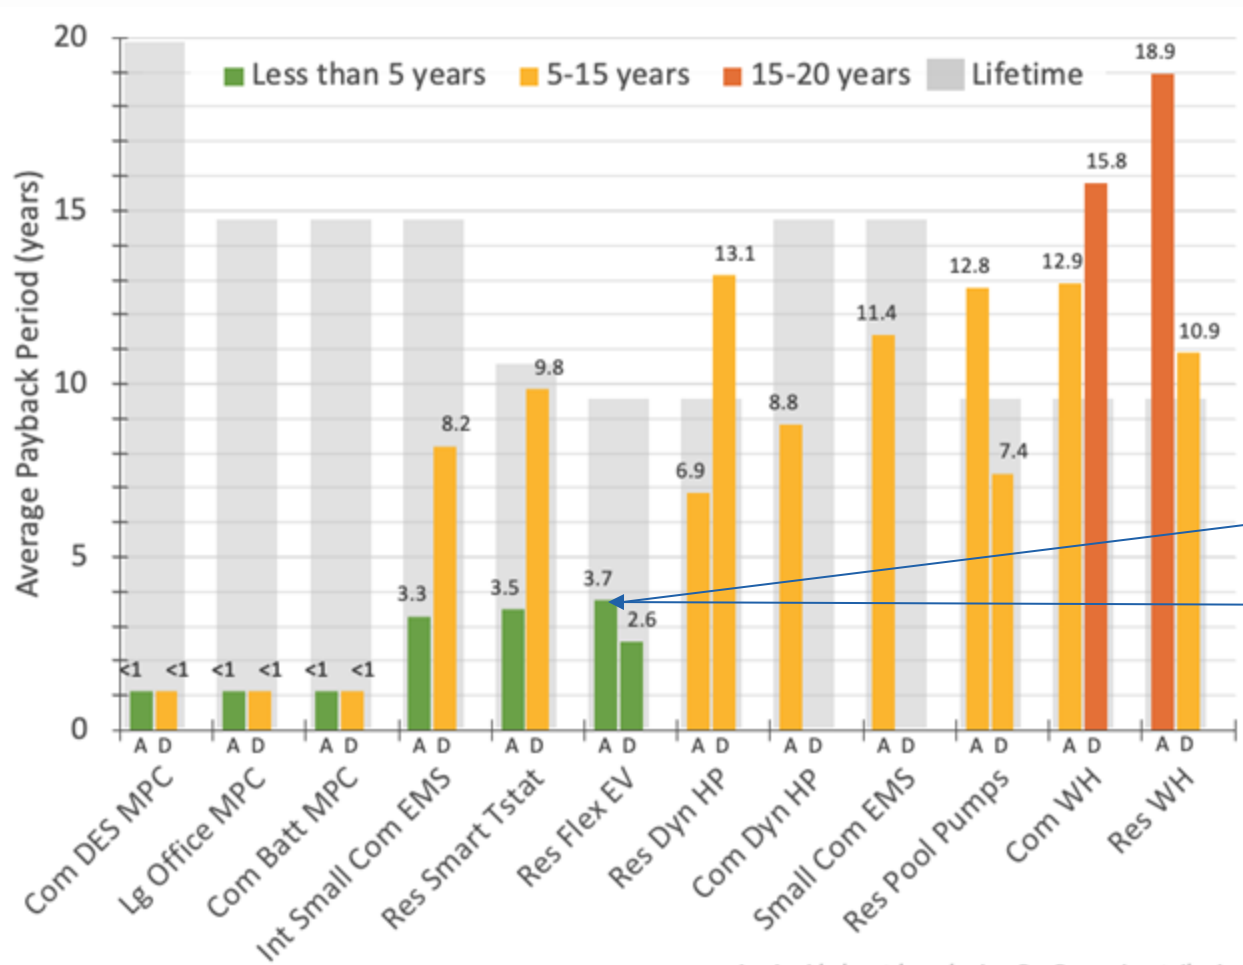

Figure 2. Event-based shed (left) and shift (right) potentials for each technology as the theoretical maximum that could be achieved with 100% adoption and enrollment.

Technologies with largest customer bases tend to offer greater grid potential and savings.

Initial results: customer value payback period

A = Avoided cost-based price; D = Dynamic retail price

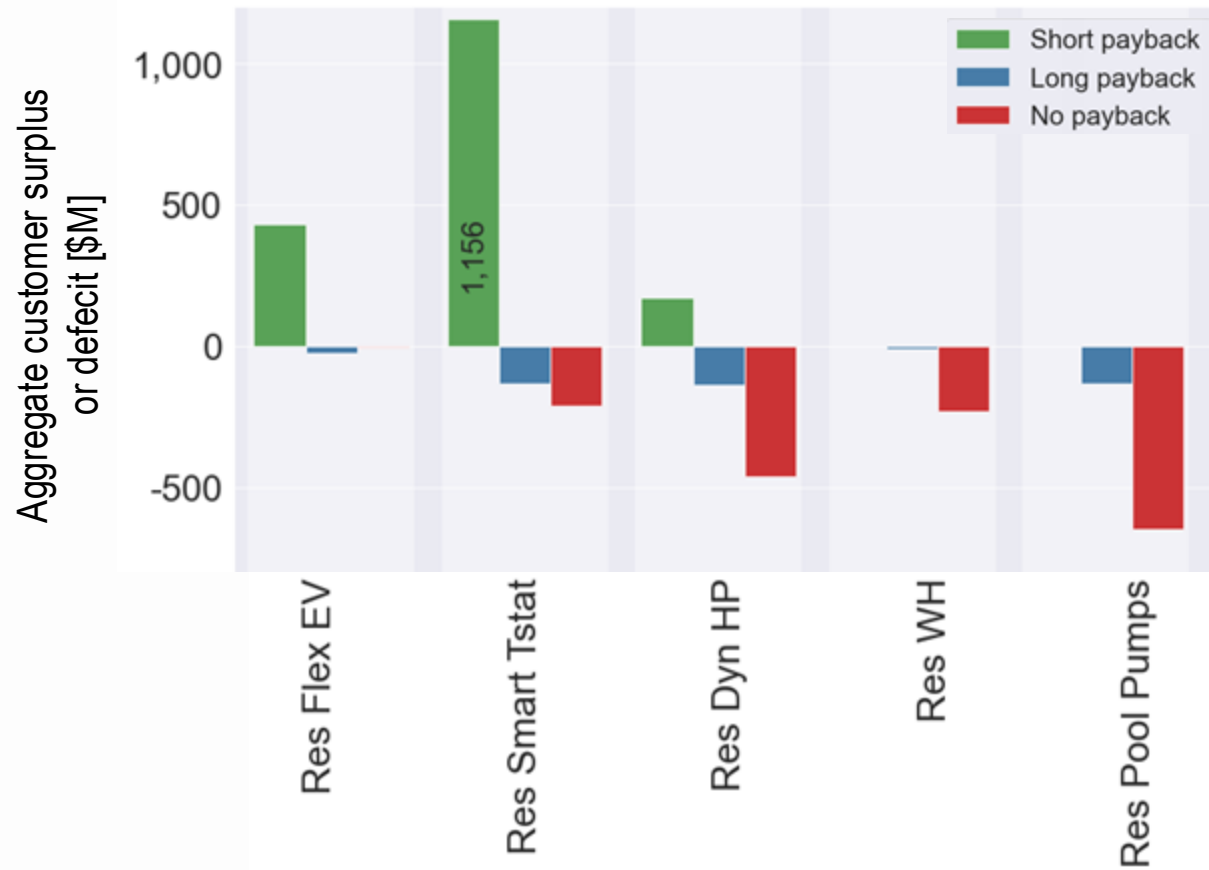

customer base range average

Deeper insights: segmenting the customer base by expected payback period

Deeper insights: customer surplus and deficit; could inform program design

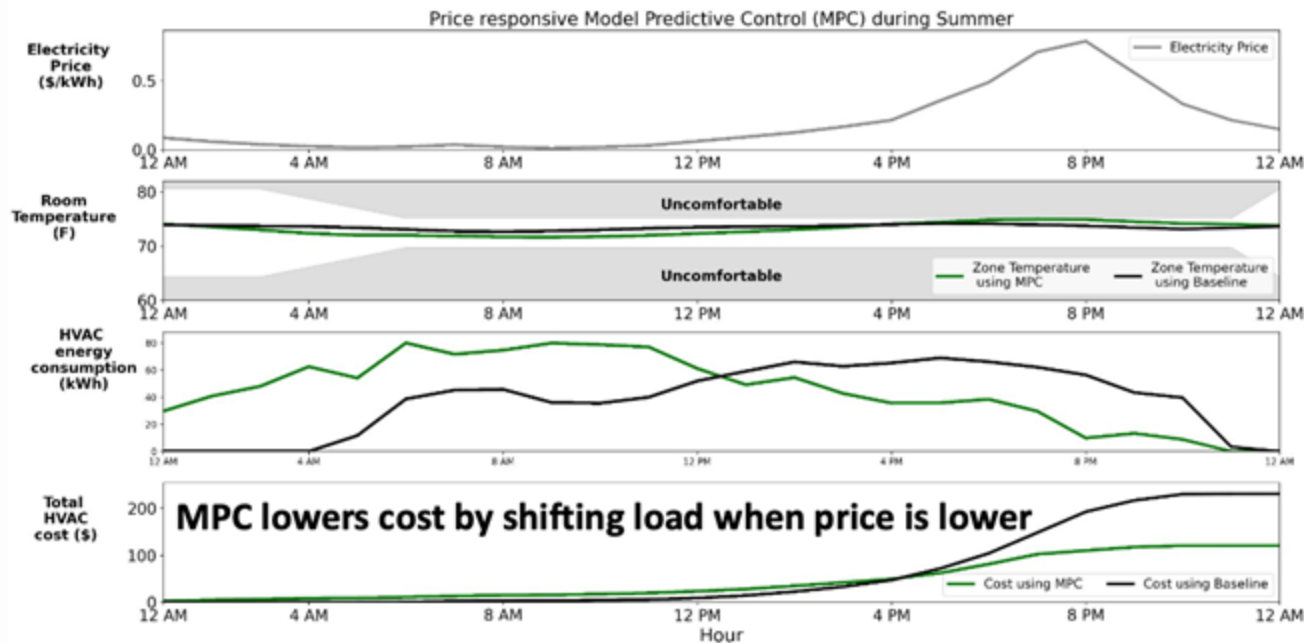

Deeper insights: cost reduction required to hit 5-year payback

Ongoing analysis to update and refine modeling assumptions

- **Smart Fans** are estimated to be much lower-cost than the estimates given in Year 1
- **Large Office MPC** is being considered over a much larger customer base, and a longer shift window, but at higher costs than originally modeled
- **Water heater** costs are being updated, and simulation models are being used to cross-check the flexibility modeling and bill savings analyzed
- And more!

MPC load shifting demonstration for Summer test

Thank you!
